

ABSTRACT

- The modern digital infrastructure heavily relies on stable and secure network communication. This project, titled "Network Troubleshooting Using Linux", was undertaken as part of our summer internship and executed by a team of four members.
- Problem statement: Changing the default HTTP port to a custom server which is often necessary for enhanced security, port conflicts, or specific server requirements.
- Solution: To approach this task, we leveraged the powerful networking capabilities of the Linux operating system. The scope of the project was divided into three core domains: HTTP configuration, Security-Enhanced Linux (SE Linux) settings, and Firewall rules management. These components are critical in ensuring that a port change does not disrupt service availability or compromise system security.
